void freeXDot (xdot*);

xdot_grad_type colorType (char*);
xdot_color* parseXDotColor (char*);
void freeXDotColor (xdot_color*);

DESCRIPTION

libxdot provides support for parsing and deparsing graphical operations specified by the xdot language.

Types

xdot
This encapsulates a series of cnt xdot operations, stored in the array pointed to by ops. The sz indicates the size of each item stored in ops. If the user sets the freefunc field, this function will be called on each item in ops during freeXDot before the library does its own clean up of the item. This allows the user to free any resources stored in the item by using an expansion of the xdot_op structure.

xdot_op
A value of this type represents one xdot operation. The operation is specified by the kind field. The corresponding data is stored in the union u, with the subfield associated with a given kind indicated by the comments.

The drawfunc field allows the user to attach a drawing-specific function to the operation, providing an object-based interface. These functions can be automatically attached during parsing by providing a non-NULL second argument to parseXDotF.

xop_kind
This type provides an enumeration of the allowed xdot operations. See http://www.graphviz.org/doc/info/output.html#d:xdot for the specific semantics associated with each operation.

xdot_rect
This represents a rectangle. For ellipses, the x and y fields represent the center of the rectangle, and w and h give the half-width and half-height, respectively. For images, (x,y) gives the lower left corner of the rectangle, and w and h give the width and height, respectively.

xdot_polyline
This type encapsulates a series of cnt points.

xdot_text
A value of this type corresponds to printing the string text using the baseline point (x,y). The width field gives an approximation of how wide the printed string will be using the current font and font size. The
**align** field indicates how the text should be horizontally aligned with the point \((x,y)\).

**xdot_image**

This denotes the insertion of an image. The image source is given by *name*. The images is to be placed into the rectangle *pos*.

**xdot_font**

The fields give the name and size, in points, of a font.

**xdot_align**

This enumeration type corresponds to the xdot alignment values -1, 0 and 1 used with the text operator, or '\l', '\n' and '\r' used in dot text.

### Functions

**xdot* parseXDotF (char *str, drawfunc_t* opfns, int sz)**

 Parses the string *str* as a sequence of xdot operations and returns a pointer to the resulting xdot structure. The function parses as many xdot operations as it can. If some unknown or incorrect input was encountered in *str*, the *ops* and *cnt* fields will reflect the operations parsed before the error, and the XDOT_PARSE_ERROR bit will be set in the *flags* field. The function returns NULL if it cannot parse anything.

If *sz* is non-zero, it is assumed to be the size of some structure type containing xdot_op as a prefix. In this case, the elements in the array pointed to by *ops* will each have size *sz*.

If *opfns* is non-zero, it is taken to be any array of functions indexed by *xop_kind*. During parsing, the drawfunc member of xop_op will be set to the corresponding function in *opfns*.

**xdot* parseXDot (char *str)**

This is equivalent to parseXDotF(*str*, 0, 0).

**void freeXDot (xdot* xp)**

This frees the resources associated with the argument. If *xp* is NULL, nothing happens.

**extern char* sprintXDot (xdot* xp)**

**extern void fprintfXDot (FILE* fp, xdot* xp)**

These two functions deparse the argument xdot structure, producing a string representation. fprintfXDot writes the output onto the open stream *fp*; sprintXDot returns a heap-allocated string.

The color string with fill and draw operations can encode linear and radial gradients. These values are parsed automatically by parseXDotF or parseXDot, with xdot_op having kind xd_grad_pen_color or xd_grad_fill_color and the value is stored in grad_color.

For an application that handles its own parsing of xdot, the library provides three helper functions.

**xdot_grad_type colorTypeXDot (char *str)**

returns the color type described by the input string.

**char* parseXDotColor (char *str, xdot_color* clr)**

attempts to parse the string *str* as a color value, storing the result in *clr*. It returns NULL on failure.

**void freeXDotColor (xdot_color* cp)**

This frees the resources associated with a value of type xdot_color.

### BUGS

Although some small checking is done on the *sz* argument to parseXDotF, it is assumed it is a valid value from sizeof applied to some structure type containing xdot_op as its first field. There can be no validation of the *opfns* argument.
